The problem is that it is returning an Int instead of a ByteArray. I'm doing this: public static T GetType(this string typeName) where T : System.Type { return (T)System.Type.GetType(typeName); } And calling it like this: obj.GetType("System.Byte[]"); Where obj is a string. I checked the type of obj is correct, but it still returns an Int when called. Is this a bug? EDIT It also has the same problem with Byte[] and String[]. EDIT 2 Also with Byte. EDIT 3 In a new question, with a more comprehensive test, I found that this is the case only when the type is Nullable. I have not tried that on purpose, but I'm guessing that it works fine on non nullable types. I'm not really sure what the purpose of the type of that method is. Is there any difference on purpose? A: I have not tested this, but I believe this is happening because your typeName is "System.Byte[]", and is in fact a string containing the name of the type you want, 1d6a3396d6

Help me make a nice animated GIF or CSS-animated circle, hyperlink, text or picture or whatever you want - and then have me mail them to you. **Java Quick Reference** This article will give you a very quick reference on the Java interface, along with a brief explanation on what each method does. **The Java Interface** There are a few major concepts that are used in the Java interface. **Classes** A class is an abstract object that contains data and methods that define the way objects of the class will be programmed. A class will use the object references, also known as instance variables, to store information about its objects, such as an object's name or a variable that keeps track of how many times it has been clicked. Instance variables must be declared inside a class to ensure that they are unique and non-nullable. **Methods** A method is a function that is stored inside a class. Methods are used to interact with and control the creation of the objects in the class. **Instance Variables** Instance variables are used to store information about objects. Instance variables can be declared anywhere inside a class, but they cannot be changed once they have been initialized. **Methods** Methods can be invoked on objects to change their state. Methods can also be invoked on objects to obtain information about them. **Instance Variables** Instance variables are declared inside a class and can be used to store information about objects. Instance variables must be initialized before they can be used and their values must never be changed after they are initialized. **Object-Oriented Programming** Object-oriented programming (OOP) allows objects to be defined in terms of each other rather than in terms of their implementations. This has many benefits. It eliminates redundant code and makes it easier to modify code because you only have to update one part of the program. It also helps to separate different concerns and improve code readability. **Reflection** Reflection is a way to programmatically access information about a type. This is done by using reflection-specific keywords and generic methods, which can retrieve information about any type without knowing the exact types. **Maths** Maths allow different types of calculations to be performed and variables to be manipulated. **Significance** The way code is structured can have a big impact on its readability and the way it performs. This is why choosing the right structure for a project
